12 A survey conducted by USDA in 1975 was designed to estimate 1974 costs
13 of production (COP) in major grain and cotton regions. Counties included
14 in the survey were primarily those with 10 percent or more of their total
15 land area in cropland. The lower limit of farm size permitted in the
16 sample, ranged from 50 cropland acres in the Southeast, to 400 cropland
17 acres in the Northwest; the upper limit of farm sizes ranged from 5,000 to
18 10,000 cropland acres, Southeast to Northwest.

20 The data gathered in the COP survey were stratified, with cropland
21 acreage as the basis for stratification. For each of 40 subregions, the
22 data were divided into one-third of the farms in each of three size
23 categories. Table 1 gives the range of cropland acreage for each size
24 group in each subregion; it also gives the number of observations in each
25 cell. The boundaries of the subregions are shown in Figure 1.

27 The acreage range was relatively narrow for the small farms, wider for
28 the medium farms, and much wider for the large farms. The wide range in
29 the latter group resulted because very large farms--with up to 10,000
30 cropland acres--were permitted to enter the sample.

32 The contribution to total production and sales by each size group is
33 not easily determined. The initial sample had been selected with
34 incomplete knowledge of the existing farm size distribution. But an

U.S.D.A., NAL

Cataloging Prep

estimate of impact by each size designation is possible by comparing the three COP survey size groups with three similar size groups delimited in the 1974 Census of Agriculture. The large, medium, and small groups defined in table 1 were found to be comparable to three farm groups (defined by the Census) with sales of \$100,000 and over (large), \$40,000 to \$99,999 (medium), and \$20,000 to \$39,999 (small). Table 2 shows the degree of comparability which is found between the Census and Survey sets of farms.

In order to hold down the size of table 2, only 5 grain producing states were considered. This particular selection was intended to typify a cross section of the important grain producing regions. In the table, under "Ag Census", a single figure represents the whole state; the associated 2 to 4 figures listed under "COP Survey" give the mean acreage of the several farm sizes in corresponding survey subregions. There is some overlapping, since subregion boundaries can go beyond state boundaries.

In Washington, the survey mean acreages turned out to be larger than the corresponding census mean acreages; in the other 4 states, the reverse was true. Otherwise, there was a surprising degree of consistency between the 2 sets of data. Hence, it seemed permissible to let census proportions of production and sales serve as broad estimates for the corresponding survey groups of farms.

The next pertinent question is: How much of each state's total grain production is covered under the Standard Industrial Classification "Cash Grain Farms?" In Washington, these farms produced 88 percent of that

63 State's wheat; in North Dakota it was 87 percent; and in Kansas 83 percent.
64 In Iowa, the same classification "cash grain farms" produced 59 percent of
65 the State's corn, while in Indiana the comparable figure was 76 percent of
66 the corn. Substantial amounts of the corn produced in the latter 2 States
67 was raised on other farm types which feed much of the grain they produce.

70 Next we can determine the proportion of grain sales made by each of the
71 3 Census groups. In Washington, the share of all grain sales by the large
72 farms was 69 percent; by the medium farms it was 25 percent; and by the
73 small farms it was 5 percent. In the other 4 states, the percentages were
74 largest in the medium size group, as follows:

77	/	<u>State</u>	<u>Large farms</u>	<u>Medium farms</u>	<u>Small farms</u>
79	/		<u>---Percent---</u>		
82	/	North Dakota	29	42	20
83	/	Kansas	37	34	17
84	/	Iowa	32	44	17
85	/	Indiana	35	35	16

87 As a generalization, we can say that large farms sold about two-thirds
88 of all the grain in Washington State; the medium and small farms marketed
89 nearly all of the remaining grain sold by cash grain farmers. In other
90 words, cash grain farms with less than \$20,000 in gross sales marketed very
91 little of the total grain sold. The California situation would likely be
92 similar to that of Washington.

94 In the Great Plains and Corn Belt, the large farm's share was only
95 about one-third of all grain sold by cash grain farms; the medium and small
96 farms accounted for about 50 to 60 percent of total grain sales.

98 Costs of Production

100 The initial COP survey was designed to determine the production costs
101 of 10 major crops. But after the farms in each subregion had been divided
102 into 3 size groups (leaving only a third as many observations per cell),
103 the categories often lacked an adequate number of observations with regard
104 to specified crops. Nevertheless, a valid comparison among farm size
105 groups was considered possible for corn in most of the eastern half of the
106 Nation, and for wheat in most of the western half of the Nation. The
107 Eastern Corn Belt was also analyzed for wheat.

110 The new "thinness" in each cell made it less possible to "average out"
111 extreme entries wherever these occurred (tending to confound the true
112 effects). Hence, the present results are necessarily more ragged than the
113 ones published in the Senate Committee Print Costs of Producing Selected
114 Crops in the United States-1974, in which all farm sizes were averaged
115 together.

117 Costs of producing corn are covered in table 3 with a tally of variable
118 costs per acre and per bushel by farm size. Only those regions and
119 subregions were included where corn for grain on dryland was a significant
120 crop. Variable costs included labor, power and equipment, materials,
121 custom services, and interest on operating capital.

123 Variable costs per acre tended to increase with an increase in farm
124 size--particularly with respect to material inputs. Value of seed went up
125 only moderately with farm size, but fertilizer and other chemicals
126 increased substantially. Fertilizer on small farms averaged \$26 per acre;
127 on medium farms \$29 per acre; and on large farms \$35 per acre. Herbicides
128 plus insecticides averaged about \$6 on small, \$8 on medium, and \$10 on

129 large farms. Unfortunately, 1974 was a bad year in the Corn Belt for
130 realizing a proper response to higher inputs. The wet spring, dry summer,
131 and early frost all hampered the yield response one might otherwise have
132 expected from the higher inputs on the larger farms. Thus, when costs per
133 bushel were calculated, particularly in the Western Corn Belt, these costs
134 tended to average higher for the large farms than for the smaller farms.
135 In the Southeast, on the other hand, where weather conditions in 1974 were
136 more nearly normal, per bushel costs were lower for large farms than for
137 medium and small farms.

140 Wheat was the other crop where a relatively valid cost comparison could
141 be made among size groups. Again, only those regions and subregions were
142 included where wheat was a predominant crop. The summary results of
143 variable costs for growing wheat are shown in Table 4.

146 Practices pertaining to wheat vary widely because the crop is grown in
147 conditions ranging from a semiarid climate in the West to a humid climate
148 in the Eastern Corn Belt. Other aspects of wheat also contrast sharply
149 with corn: Some wheat is planted in the fall, some in the spring; some is
150 planted on summerfallow, some on recrop ground; there are several distinct
151 classes of wheat and all respond differently to given influences. With
152 this lack of homogeneity in the "wheat" covered in table 4, the results are
153 inclined to be less determinate, and analytic results seem more tentative
154 than the results of the corn analysis based on the previous table.

157 The amount of fertilizer applied per acre of wheat ranged from \$0 to
158 \$28 going from the dry West to the humid East. But among the size groups,
159 the differences in fertilizer application for wheat were smaller than for

160 corn--\$4.83/acre for small farms; \$6.55/acre for medium farms; and
161 \$7.69/acre for large farms. The direct correlation between farm size and
162 fertilizer use was offset by the indirect correlation between size and 2
163 other important inputs--labor and seed. Small farms used 20 percent more
164 labor and 23 percent more seed per acre than the large farms.

167 The large farms in the semiarid parts of the Great Plains were the only
168 group of farms capable of holding variable costs below \$30 an acre. Other
169 subregions of the Great Plains and the Pacific Northwest had costs between
170 \$30 and \$40 per acre. Eastern Kansas, the Texas Blackland, and Northern
171 Missouri had costs between \$40 and \$50. The Eastern Corn Belt, the Red
172 River Valley, and the Sacramento Valley averaged \$50 to \$60 per acre.

175 Per bushel costs ranged even wider--from less than 90 cents in Eastern
176 Nebraska (where the wheat had matured by the time the severe drought had
177 set in) to \$4.69 in the Texas High Plains where drought had been fully
178 reflected in the wheat yields.

180 Other Cost Analysis

182 The dollar values attached to most cost components were determined by
183 engineering formulas--with the help of physical input information obtained
184 from the survey. But the dollar value of 2 significant components--
185 fertilizer and herbicides--was obtained directly from respondents'
186 estimates. These values are listed by size of farm for 4 grain crops.
187 tables 5 through 8 provide information for corn, sorghum, barley and wheat.

190 Patterns are hard to derive from the results shown in these tables.

190 But as observed earlier, the number of observations often were insufficient
192 to attenuate the effects of oddball entries--the extreme entry which creeps

193 in through error or chance. Hence, the raggedness of the results. And
194 thus, for example, we should not rely on irrational results such as that in
195 the Sacramento Valley, where large farms indicated use of only 40 percent
196 as much fertilizer on their corn as did the small farmers. The actual
197 situation is probably quite different.

200 Many relevant variables were not taken into account in this analysis
201 where only 2 factors could be considered at one time, nor were effects of
201 the other factors controlled. For example, the percent of acres irrigated,
202 or the amount of irrigation water applied, had a substantial bearing on
204 yield results. Yet these factors could not be accounted for in tables 5
205 through 8. The limited number of observations did not permit their effects
206 to be reflected in a cross-classification type of analysis.

208 In general, it might be said that the amount of fertilizer applied is
209 pretty much a function of the availability of moisture expected for the
210 growing crop. The relative profitability of the crop to which fertilizer
211 is applied is also a factor. Thus, corn tends to receive more fertilizer
212 than sorghum and wheat more than barley, as a general rule.

215 Only corn received a substantial amount of herbicides, particularly in
216 the Eastern Corn Belt and in the Southeast. The other 3 crops received \$2
217 an acre or less, except for a slightly higher rate applied to wheat in the
218 Palouse area of Washington and to sorghum in Eastern Kansas.

220 Seed is another sizeable input required for raising crops. Where home
221 grown seed was used, the value was based on the market price for grain at
222 the time of seeding. An additional charge was added to cover seed cleaning
223 and treatment expenditures.

225 Where seed was purchased, the price used was the purchase price given
226 by the farmer. Seed purchases are made when home grown seeds are
227 considered less profitable, or when new varieties are being introduced into
228 the farming operation. Tables 9 through 12 give the proportion of total
229 corn, sorghum, barley, and wheat seed which had been purchased to produce
230 the 1974 crop.

232 Table 9 shows that nearly all seed corn in the Corn Belt was purchased.
233 GP-10 (Central Nebraska) is regarded here as part of the Corn Belt.
234 Similarly the Coastal Plains of the Southeast also bought nearly all their
235 seed. The remainder of the Southeast purchased 50 to 70 percent of their
236 seed. The subregions west of the Corn Belt used home grown seed for half
237 to nearly all of their seed needs.

239 Table 10 shows that the subregions of Texas and Eastern Kansas had the
240 highest purchases of sorghum seed--ranging from 75 to 95 percent of total
241 used. Several other important sorghum subregions had purchased roughly
242 half their 1974 seed. The remaining subregions which planted relatively
243 small amounts of sorghum used home grown seed for two-thirds to all their
244 needs.

246 Table 11 shows that in the case of barley, seed purchases exceeded home
247 grown seed in only one area--the Washington Palouse. Southeastern Idaho,
248 the San Joaquin Valley, Arizona, and the Red River Valley purchased around
249 40 percent of their needs. The remaining areas purchased only 5 to 20
250 percent of the seed they used.

252 Table 12 shows that in the case of wheat, the Western States were high
253 in the proportion of seed they had purchased. The only other subregion

254 buying more than half its seed wheat was the Red River Valley. The
255 remaining subregions ranged from half to a negligible amount, in the
256 proportion of seed they had purchased.

258 For all 4 grains, the size of farm did not seem to be a significant
259 variable in the proportion of seed that was purchased.

261 Other Farm Characteristics

263 The main objective of the survey was to determine production costs, but
264 other aspects of farming were also revealed. One investigation led into
265 the disposition of grains: Determining the ratio of cash grain sales to
266 amounts which were fed on the farms where produced. Table 13 shows that in
267 the Corn Belt and Southeast, up to 50 percent and more of the grains were
268 not sold but were fed right on the farm. By contrast, in the region west
269 of the hundredth meridian the farmers sold nearly all of the grain they had
270 produced.

272 Table 13 may leave the impression that farm animals play a small role
273 in western agriculture because an insignificant portion of the grain was
274 fed where produced. But when examining average amounts paid out for
275 purchased feed (table 14), it is apparent that on at least some western
276 farms, farm animals make up a substantial part of the business.

278 Some outlays for feed probably were for winter maintenance of ranch
279 animals. But in certain subregions (Western States and Western Great
280 Plains), the size of payments for feed were so large that we must assume a
281 connection with feedlot cattle finishing. This line of reasoning is
282 further supported in table 15 where it is revealed that relatively large
283 sums were paid out for the purchase of feeder livestock.

286 Besides purchases for the feedlot, large numbers were bought to serve
287 as stockers for grazing winter wheat and some other cover crops. The large
288 purchases made for GP-1 and GP-4 farms, no doubt, were largely for stockers
289 to run on winter wheat. In the southern third of the Nation, a number of
290 other crops are also winter grazed.

292 Capacity for Grain Storage

294 The various capacities for on-the-farm storage are given in table 16.
295 They show a great deal of variation among the regions as well as within the
296 regions. The largest variations were within the Texas-Oklahoma area. The
297 area with the largest amount of farm storage was the Northern Plains,
298 including Nebraska but not Kansas. The Corn Belt ranked second, and this
299 region showed the least amount of variability among subregions, especially
300 in the Western Corn Belt.

302 Table 17 gives the total outlays for rented grain storage. These
303 outlays generally consisted of payments by farmers to country elevators.
304 The largest amounts paid out for storage were in the Palouse part of the
305 Pacific Northwest (W-5), parts of the Central Plains (GP-1, GP-2, and GP-
306 4), the cash grain area of the Corn Belt (NC-9), and the western part of
307 the Mississippi Delta (SC-2).

309 Capacity for Fuel Storage

311 A measure of on-the-farm fuel storage was obtained for diesel,
312 gasoline, and LP gas. Tables 18, 19, and 20 give the gallon capacity of
313 on-farm storage for these fuels.

315 The Western States store the largest amount of fuel because their
316 larger farms consume more, and because of the more intensive farming

317 practiced in California and Arizona. In the other regions, fuel stored is
318 pretty much a function of farm size, relative fuel prices, ready
320 availability of each type of fuel, and amounts used for special purposes
321 such as irrigation, grain drying, etc.

323 A check on shop and shop related equipment showed that Western States
324 and Western Great Plains operators appear more inclined to repair their own
325 machinery. Table 21 shows their shop type of investments were greater than
326 for farms further to the east. These western farms also have a higher
327 investment in farm machinery. This same pattern was found within
328 subregions--amounts invested in shop and related equipment tend to vary
329 with farm size, and therefore with the size of the machinery complement.

332 Operator Characteristics

334 In nearly all cases, the person interviewed had chief management
335 responsibility for the farming operation. The bulk of these operators
336 identified farming as their chief occupation. The number of weeks out of
337 the year not devoted to the farm are given in table 22. Operators even in
338 the small farm category spend less than half their time on off-farm
339 activities. However, small farmers in Southern Michigan (NC-10) came close
340 to spending 50 percent of their time off the farm--23 weeks out of the
341 year.

343 We can conclude that part-time farms were not uncommon in the survey
344 sample. Even the medium size farms had operators in some regions who
345 reported substantial off-farm employment. The off-farm opportunities were
346 greatest in the Southeast, the Eastern Corn Belt, Texas, and the Central
347 Kansas-Oklahoma area. A more deliberate screening of the sample would have

348 been required if only full-time operators were to be included among those
349 interviewed.

351 The education of the operators is given in table 23 and shows that
352 operators in the Western States averaged nearly one year beyond high
352 school. The operators in the Southeast averaged the least education--a
353 level about midway between grade school and high school graduation. The
356 operators at the northern and southern ends of the Eastern Great Plains
358 also averaged less education than most others. For the U.S. as a whole,
359 the small farmers averaged 10.7 years of schooling; the medium 11.2 years,
360 and the large 12.0 years.

362 Other studies have supported the findings that, on an average, large
363 farm operators are better educated and average somewhat younger than
364 operators of smaller farms. Younger operators tend to inherit substantial
365 amounts of capital which they can apply to their farming operations.
366 Sometimes they also have an interest in business ventures located in the
367 same general area as their farm.

369 Small and medium farm operators, on the other hand, tend to have less
370 capital, as well as less education and managerial capacity. There are also
371 more operators in this group who are semi-retired; hence, the farm occupies
372 their time and plans less fully than the operators whose planning horizons
373 extend over decades.

375 Tenure patterns, covered in table 24, show a generally greater
376 proportion of ownership among the small farmers. But such a pattern is
377 less apparent in subregions where cash grain production is emphasized. For
378 example, even the small farmer seems to rent up to half of his land in the

379 drier parts of Eastern Washington-Oregon (W-4); the drier parts of Kansas-
380 Colorado-Oklahoma-Texas (GP-1); Central Kansas (GP-2 and GP-4); the rice
381 area of Texas (SC-4); and the cash grain area of the Corn Belt (NC-9).
382 Cash grain farming, of course, requires relatively more land, and the
383 incentive is to rent where land ownership is limited by lack of capital and
384 for other reasons.

386 Tenure is also a function of geography, religion and ethnicity of the
387 settlers, and the degree to which farm enlargement has progressed in any
388 given area. Thus, with the passage of time, ownership may shrink in the
389 Northern Plains and Southeastern Idaho. These areas were settled more
390 recently than others in the study.

392 Remarks

394 The foregoing discussion is based on a subclassification or cross
395 classification type of analysis. This method of analysis is concerned with
396 the relationship between a dependent variable (e.g. variable costs) and
397 usually two cross-classifying independent variables (e.g. farm size and
398 geographic location).

400 Since there are normally several important factors which influence
401 costs, there is need for a procedure that studies the influence of several
402 independent variables simultaneously. The cross-classification system can
403 serve in multifactor analysis as well as in 2 factor analysis if a large
404 number of observations are available. But there is a practical limit to
405 the number of observations which surveys on production costs can collect,
406 in view of the high cost of sample surveys and the task of getting the
408 cooperation and forbearance of respondents.

410 A multivariate analysis of this set of data is being considered at this
411 time. It is a technique which not only allows for a simultaneous
412 consideration of several factors in 1 operation, it also permits individual
413 examination of 1 factor while the influence of other factors is controlled.
414 Failure to control the effects of certain interrelated factors when
415 examining the effect of a particular factor can cause parameter estimates
416 to go wide of the mark. Also, the errors of observation in this survey, as
417 in other similar surveys, can distort the estimates of effects being
418 measured.

Figure 1
